

MEASURED — CARE SET AND PRODUCT-TERM COUNT VERSUS FAN-IN

Conditions: 256 nodes, $M = 4$ target states, radius $h = 3$, two-level minimisation by the Berkeley espresso program. At fan-in 24 and above the fully-specified table cannot be enumerated at all, so no comparison column exists there.

The saving is in what has to be SPECIFIED, and only then in the term count that follows from it.
